Portfolio Collaborative Construction Intro

Complete implementation prompt • 10 designer cursors • 30–35 seconds

MASTER PROMPT

Act as a senior React motion-design engineer and frontend performance specialist. Inspect the supplied existing portfolio project, then implement a 30–35 second collaborative construction intro that visually builds the REAL existing portfolio and transitions into the actual functioning website. This is an animation layer, not a redesign, mockup, fake Figma clone, or replacement site. Preserve existing content, section order, typography, colors, assets, layout identity, routes, links, responsive behavior, and functionality. Never invent sections or content.

PROJECT AUDIT

Inspect project structure, package.json, React/Vite/Tailwind setup, routing, theme system, Hero and section components, animation libraries, custom cursor, global styles, breakpoints, and image/video assets before coding. Identify actual sections and their order. Reuse installed dependencies; integrate cleanly and avoid wholesale component replacement.

RESPONSIVE RULES

Use effective layout viewport width, not user-agent or pointer type. At >=1024 CSS px, run the full intro—including a phone using Desktop Site when its effective viewport is desktop-width. Below 1024 CSS px, skip the desktop intro and show the existing website with a subtle blur-to-clear fade-in. Every eligible desktop-width refresh replays the full intro; do not suppress with session/local storage. Touchscreen alone must not disable the intro.

THEME & OPENING

Resolve the saved/current theme before first visible paint; never flash light theme before dark. Preserve theme preference/toggle. Open on deep black with extremely subtle violet ambient light. No busy particles, grids, editor chrome, or obvious gradient circles.

TEN DESIGNER CURSORS

Render exactly ten custom collaborator cursors with consistent premium design language, subtle pointer shape variations, professional coordinated colors (blue, violet, teal, amber and harmonious shades), restrained glow, short fading trails. Use titles only—no personal names/usernames: UI Designer; UX Designer; Visual Designer; Layout Designer; Typography Designer; Motion Designer; Interaction Designer; Graphic Designer; Frontend Designer; Creative Director. Each has stable identity/color and a primary specialty, but can assist with related tasks. Compact labels show role + live action, e.g. “UI Designer · Building Hero”, with occasional “✓ Done”. All ten remain present; active cursors are prominent and idle cursors subtly dim. Avoid label collisions and covering content.

COLLABORATION & MOVEMENT

All ten appear clustered, then spread into dynamic teams of typically 2–4 based on task complexity. Use purposeful independent actions, coordinated group work, handoffs, and regrouping. Intelligent smooth curved paths, natural acceleration/deceleration, realistic pauses, and collision avoidance. No random wandering, teleporting, sudden jumps, robotic zigzags, or pointless loops. Synchronize camera and cursor motion.

CONSTRUCTION VISUALS

Show the actual portfolio being assembled. Never show Figma/IDE/editor UI: no toolbar, sidebar, menus, inspector, fake logo, or editor frame. Only cursors, compact role/action labels, and temporary selection/resize feedback. Use actual website layout as the base; temporary camera framing/spacing may clarify actions, but restore exact original layout before reveal.

ULTRA-DETAILED ELEMENT BUILD

Text uses realistic typing/reveal without rewriting copy. Images use restrained fade/scale and actual placement/crop adjustments. Videos reveal their real frame/poster with a subtle cinematic transition; do not autoplay or cause unnecessary decoding/network load. Cards show cursor-led drag/place, resize, alignment. Buttons snap into position while preserving real labels/links. Show spacing, alignment, color, border, shadow, layer ordering and component refinement only where they genuinely exist. Selection is minimal: colored outline and role label; handles only during resize. Click feedback: small ripple and tiny scale response; drag/drop/resize feedback is contextual.

SECTIONS & CAMERA

Build real sections in exact existing order/content. Hero first; then multiple teams build remaining existing sections in parallel. Do not assume About/Skills/Projects/Education/Experience/Contact exist unless present. Use actual assets only. Camera begins wide, gently zooms toward Hero, pans between nearby sections, uses gentle zoom-out/pan/zoom-in for distant sections, frames parallel work calmly, zooms out for final overview, then settles at actual Hero viewport. No abrupt cuts, black flashes, jerky pans, or editor screens.

TIMELINE: 30–35 SECONDS

0–3s: black/violet atmosphere and ten cursors appear clustered. 3–7s: cursors spread and form teams. 7–14s: detailed Hero construction. 14–24s: remaining real sections built collaboratively. 24–29s: micro-adjustments, alignment, refinement and polish. 29–35s: completed overview and cinematic transition to actual website. Timing is flexible to actual portfolio complexity, but total must remain 30–35 seconds. No progress bar, percentage, loading indicator, or progress label.

TRAILS & PERFORMANCE

Use short glowing trails and very few tiny fading particles; intensity may respond to speed and fades quickly at rest. Strict particle cap. Preload critical fonts, Hero media and essential styles; progressively load remaining assets. Do not reveal a section until its required assets are ready or fallback is available. Reserve media dimensions to prevent layout shift. Avoid per-frame React re-renders; use requestAnimationFrame and transform/opacity-based animation or existing animation stack. Avoid layout thrashing, expensive filters, huge blur layers, unbounded particles, and unnecessary video decoding. Adapt glow/particles/concurrent nonessential effects on weaker devices while preserving story and duration. Clean up all listeners, observers, frames, and media resources.

INTERACTION & FINAL REVEAL

Temporarily block ordinary page scrolling and pointer interaction during intro to preserve the sequence, without permanently disabling browser navigation or leaving focus unusable. On completion restore scroll, pointer interaction, and sensible focus. Designers finish alignment; elements settle; cursors, trails, labels, outlines, handles and overlays fade away. Resolve into the actual functioning React site—not a screenshot. Existing buttons, links, navigation, animations, forms, video controls and scrolling must work.

FAILURE FALLBACK

If initialization/assets/animation fail or performance degrades severely, safely terminate intro and reveal actual website with graceful transition. Use bounded timeouts and robust cleanup. No infinite loading/retry loops, blank screen, locked body scroll, disabled pointer events, or stale overlays.

IMPLEMENTATION & TESTS

Use existing React/Vite/Tailwind and installed animation stack (including Framer Motion/GSAP if present); avoid unnecessary dependencies. Keep cursor rendering/choreography, camera timeline, overlays, responsive gating, theme bootstrap and fallback modular. Test: desktop >=1024; phone Desktop Site >=1024; normal mobile <1024; replay on every desktop refresh; no theme flash; ten distinct cursors and collision-free labels; adaptive performance; failure fallback; restored site interactions; final fidelity to original content/design. Report files changed, implementation decisions, tests actually run, and limitations. Never claim unrun tests passed.
